Storage tiers

Hot data lives in memory so reads return in microseconds. Warm data sits in a network cache, a little slower but shared between instances. Cold data is read from disk and is the cheapest to keep around for audits and backups.

Eviction policy matters as much as capacity. Least recently used entries leave first, which suits most read-heavy workloads. Set a maximum size per tier so one tenant cannot fill the whole cache.

Tier	Latency	Cost
Memory	0.1 ms	high
Redis	0.5 ms	medium
Disk	8 ms	low
